# ANT COLONY OPTIMIZATION WITH REINITIALISATION 

M. Ciba, I. Sekaj

Institute of Control and Industrial Informatics, Faculty of Electrical Engineering and Information Technology, Slovak University of Technology in Bratislava, Ilkovičova 3, 81219 Bratislava, Slovak Republic

#### Abstract

Ant colony optimization (ACO) represents an efficient tool for optimization and design of graph oriented problems. It is a multi-agent meta-heuristic approach. It is used for logistic, vehicle routing, minimal path search and many other problems which can be transformed to graph representation. The paper is devoted to extensive simulation tests and performance comparison of new developed variants based on reinitialization with the most efficient ACO variant of Kumar, et al. [2] in the Matlab environment.

## 1 Principles of the ACO algorithm

During the search process each ant set off from ant colony, which represents the starting position and start to move and search for food. The aim is to find the shortest way to the food location. As ants are passing the terrain (graph) they mark the used routes (arcs of the graph) by a chemical substance called pheromone. On their way back they use the same way from which abundant loops has been removed. The amount of pheromone (1) $\Delta \boldsymbol{\tau}_{i j}^{k}(t)$ they produced is inversely proportional to the tour length $L^{k}(t)$

$$
\Delta \tau_{i j}^{k}(t)=\left\{\begin{array}{cl}
Q / L^{k}(t) & i f(i, j) \in \mathrm{T}^{k}(t)  \tag{1}\\
0 & \text { if }(i, j) \notin \mathrm{T}^{k}(t)
\end{array}\right.
$$

$\mathrm{T}^{k}(t)$ is the tour generated by $k$-th ant, $Q$ is a constant and tuple $(i, j)$ denotes beginning and termination node of a graph arc. The amount of pheromone passed by each ant represents a quality of the particular solution. All pheromone tracks (2) are preserved by arcs of the graph

$$
\begin{equation*}
\tau_{i j}(t+1)=\rho \tau_{i j}(t)+\sum_{k=1}^{m} \Delta \tau_{i j}^{k}(t) \tag{2}
\end{equation*}
$$

where $\rho \in(0,1)$ is the pheromone persistence ( $\rho-1$ is evaporation rate) and $m$ is the number of ants. Evaporation rate is a user adjusted parameter and affects pheromone durability; i.e. how long the acquired information will be available. Too high values causes random search, too low values get algorithm stock in local optimum.

An ant in each node has to make a decision which arc to take. At the beginning when no pheromone values are available heuristic values $\eta_{i j}$ takes dominance. Later the ant uses probability selection rule to choose the next arc according to

$$
\begin{equation*}
p_{i j}^{k}(t)=\frac{p_{i j}(t)}{\sum_{i \in N_{i}^{k}} p_{i j}(t)} \tag{3}
\end{equation*}
$$

where $p_{i j}^{k}(t)$ is probability the ant $k$ chooses the arc $(i, j)$ from the neighbourhood $N_{i}^{k}$ of node $i$ except the node visited previously. The more pheromone is located on particular arc, the more attractive it is for the ant. The probability $p_{i j}(t)$ of choosing the particular arc $(i, j)$ depends on pheromone $\tau_{i j}(t)$ and the heuristic $\eta_{i j}$ values it has associated according the equation

$$
\begin{equation*}
p_{i j}(t)=\frac{\tau_{i j}^{\alpha}(t)+\eta_{i j}^{\beta}}{\sum_{k \in N_{i}}\left(\tau_{i k}^{\alpha}(t)+\eta_{i k}^{\beta}\right)} \tag{4}
\end{equation*}
$$

where $\alpha$ and $\beta$ are weight parameters which represents balance between the user preferred search area and ant's gathered knowledge. Heuristic values $\eta_{i, j}$ are significant only at the beginning of the search process when pheromone values are low. They serve as user input to navigate the search process to preferred area.

To the disadvantages of ACO algorithms belong (i) many user tuneable parameters and (ii) the selection pressure. While the first one is in nature of the algorithm, to the second one many papers have been devoted. Let's mention MAX-MIN ant system (MMAS) [3, 4] in which pheromone values are restricted to an interval $\left(\tau_{\min }, \tau_{\max }\right)$; identification the most versatile values for ACO parameters [5]; a modification of Ant system (AS) called $\mathrm{AS}_{\text {rank }}$ [6] where only $\sigma-1$ ants are allowed to update their pheromone track; ant colony system (ACS) with pseudo-random proportional rule [7] in which random uniformly distributed variable $q \in\langle 0,1\rangle$ is compared with a tuneable parameter $q_{0} \in\langle 0,1\rangle$. If $q \leq q_{0}$ then

$$
p_{i j}^{k}(t)=\left\{\begin{array}{cc}
1 & \text { if } j=\arg \max p_{i j}  \tag{5}\\
0 & \text { otherwise }
\end{array}\right.
$$

else the probability selection rule (3) is applied; random selection applied to $\mathrm{AS}_{\text {rank }}$ [8] where random selection rate $r$ is the probability of random selection and it represents an user parameter which adjust balance between exploration and exploitation; prevention of quick convergence (i) and stagnation avoidance (ii) mechanisms applied to AS [2].

The prevention of quick convergence mechanism is based on pseudo-random proportional rule [7], but the tuneable parameter $q_{0}$ is dependent on algorithm iteration

$$
\begin{equation*}
q_{0}=\frac{\log _{e}(N C)}{\log _{e}\left(N_{-} \max \right)} \tag{6}
\end{equation*}
$$

where NC is the current iteration and $\mathrm{N} \_$max is the termination iteration.
The stagnation avoidance mechanism is based on comparison of randomly generated quantity $q \in(0,1)$ with probability $p_{i j}^{k}(t)$ of selected arc. If $q \geq p_{i j}^{k}(t)$, then choose the next node randomly. This occurs in later stages of the search process, where pheromone values tend to be high, and thus chance of further exploration is low.

## 2 Re-initialization approach in ACO

Re-initialization applied to ACO called ACO with macro cycles ( $\mathrm{ACO}_{\mathrm{MC}}$ ) has been introduced in [9]. The re-initialization prevents pheromone saturation and subsequently the search process from being entrapped in local optimum. The idea is based on pheromone accumulation behaviour (Fig. 1) and its limit value is

$$
\begin{equation*}
\tau_{i j}(\infty)=m \frac{Q}{L^{+}(1-\rho)} \tag{7}
\end{equation*}
$$

where $Q$ is a constant from equation (1), $\rho$ is pheromone persistence from equation (2) and $L^{+}$is the length of the most attractive path $T^{+}$. The most attractive path is the path with the highest pheromone values.

Figure 1: Simulation of pheromone accumulation for parameters $m=2, Q=1, L^{+}=5$ and $\rho=0.95$ gets limit value 8 .
According to the pheromone accumulation, let us recognise three phases of search process: beginning (Figure 1, $t \in\langle 0,40\rangle$ ), saturation ( $t \in\langle 40,80\rangle$ ) and stagnation ( $t>80$ ). The search process is re-initialized at the beginning of the saturation phase. To determine the transition between the beginning and the saturation phase equation (8) cannot be used, since the length of the most attractive path nor number of ants constituting is not known. However, derivation of the pheromone accumulation can be used instead

$$
\begin{equation*}
0.01 \bar{\tau}(t)=\frac{d \bar{\tau}(t)}{d t} . \tag{8}
\end{equation*}
$$

Low derivation values indicate the saturation phase. The transition according to the equation (7) is depicted in Fig. 2.

Figure 2: Bounds between beginning and the saturation phase.
Such a search process is divided into low number of macro cycles. New search process is not entirely independent from the previous one; it benefits from diminished picture of pheromone information acquired in the previous macro cycle, while the first one relies on the heuristic values provided by the user. For that purpose the projection according the following equation is used

$$
\begin{equation*}
f\left(\tau_{i j}(t)\right)=\left(s_{i j}(t) d_{i j}(t)+\bar{\tau}(t)\right) r c \tag{9}
\end{equation*}
$$

where $\bar{\tau}(t)=\sum_{i j \in G} \tau_{i j}(t)$ is mean value of the pheromone, $s_{i j}(t)=\operatorname{sign}\left(\tau_{i j}(t)-\bar{\tau}(t)\right)$ is difference sign, $d_{i j}(t)=\log _{10}\left(1+\left|\tau_{i j}(t)-\bar{\tau}(t)\right|\right)$ is non-linear transformation of the difference and $r c=m \frac{Q}{L^{+}}$is a reducing coefficient. The prevention of a quick convergence from Kumar, et al. (2003) is used, but value of the $q_{0}$ parameter is constant during one macro cycle. For subsequent macro cycles it is

$$
\begin{equation*}
q_{0} \in\left(q_{01}, q_{02}, \ldots, q_{N}\right) ; \quad q_{0 i=1}-q_{0 i}=\frac{P_{\max }-P_{\min }}{N-1} \tag{10}
\end{equation*}
$$

where $P_{\max }$ and $P_{\min }$ corresponds to the limits of the interval $\langle 0.1,0.9\rangle$ respectively and $N$ is number of macro cycles.

Further modification of $\mathrm{ACO}_{\mathrm{MC}}$ is a variable value for $q_{0}$ parameter during one macro cycle. It is called ACO with variable macro cycles $\left(\mathrm{ACO}_{\mathrm{VMC}}\right)$ [10]. Since the length of macro cycle varies, the mechanism capable of monitoring the search process within a single macro cycle is based on difference between mean pheromone value $\bar{\tau}(t)$ and its derivation $\frac{d \bar{\tau}(t)}{d t}$ according to equation

$$
\begin{equation*}
q_{0}(t)=1-k\left(\frac{d \bar{\tau}(t)}{d t}-0.01 \tau(t)\right) \tag{11}
\end{equation*}
$$

where parameter $k=\frac{1}{d \bar{\tau}(t) / d t}$ insures that $q_{0}$ varies from 0 to 1 .

## 3 Case study

The above two modifications of the ACO algorithm with re-initialisation were tested and then compared with the most efficient algorithm $\mathrm{ACO}_{\text {KTS. }}$. Common parameters for both algorithms were set in accordance with [5] and are listed in the Table 1.

Table 1: COMMON ACO PARAMETERS SETTINGS

| Initial pheromone value $\tau_{i j}(0)$ | 0.1 |
| :--- | :--- |
| Weight of pheromone information $\alpha$ | 0.5 |
| Heuristic values $\eta_{i j}$ | 0.1 |
| Weight of heuristic information $\beta$ | 0.1 |
| Pheromone persistence $\rho$ | 0.95 |

During the test available resources like number of ants or number of cycles were changed. For each setting 500 trials were performed for statistical significance. The test was performed on two different graphs.

Since the $\mathrm{ACO}_{\text {KTS }}$ does not use macro cycles, the first ACO versions with macro cycles were tested. Then the mean of the termination cycles from the best result was determined and considered as the input parameter for $\mathrm{ACO}_{\text {KTS }}$.

### 3.1 Test on the 50 node graph

The first graph is a randomly generated graph with 50 nodes and 200 arcs. Node coordinates $x, y$ are from range $\langle 0,1\rangle$ and each arc value $c_{i j}$ is equal to the length of the arc $a_{i j}$. This makes the difference between $c_{i j}$ values very small. The graph is a symmetrical multi-graph (Fig. 3) with the depicted shortest path found during the test between start node $n_{s}=2$ and end node $n_{e}=31$ (green).

Figure 3: The 50 node graph with the minimal path - green
During the test the value of the reducing coefficient $r c$ was changed to investigate the impact on the performance. Instead to determine its value form (9) different constant settings are used according to the Table 2 .

Table 2: REDUCING COEFFICENT SETTINGS

| First set | $r c=$ var iable |
| :--- | :--- |
| Second set | $r c=0.3$ |
| Third set | $r c=0.2$ |
| Fourth set | $r c=0.1$ |
| Fifth set | $r c=0.05$ |

One test set is constituted by a couple of different groups with different available resources according to the Table 3.

Table 3: AVAILABLE RESOURCES PER GROUP

| Group | Ants | Macro cycles |
| :---: | :---: | :---: |
| 1 | 2 | 2 |
| 2 | 2 | 4 |
| 3 | 2 | 6 |
| 4 | 4 | 2 |
| 5 | 4 | 4 |
| 6 | 4 | 6 |
| 7 | 6 | 2 |
| 8 | 6 | 4 |
| 9 | 6 | 6 |

### 3.1.1 Minimal path search results

For test evaluation the following metrics were used. The cardinality $n$ is the number of occurrences of the global optimum in 500 repetitions. $\bar{c}_{b e s t}$ is the arithmetic mean of the cycle numbers where the algorithm has found the best solution and $\bar{c}_{t e r}$ is the arithmetic mean of the termination cycle numbers.

During the test all algorithms and variants with different settings were able to find the global optimum given by the minimal path $T_{\min }=\{2264722182431\}$ and its length $L_{\min }=1.26023855725949$. The only difference was in cardinality $n$ and the mean value of the best cycle number $\bar{c}_{b e s t}$ and of the termination cycle number $\bar{c}_{t e r}$.

The results of minimal path search show Tables $4-14$. There is a separate table for each set where each line represents statistic values from 500 trials.

| 8 | 192 | 45.406 | 94 |
| 9 | 252 | 66.313 | 141 |

Both ACO variants with macro cycles achieved the best performance with reducing coefficient which was set to variable. The simple variant $\mathrm{ACO}_{\mathrm{MC}}$ outperformed $\mathrm{ACO}_{\mathrm{VMC}}$ in the most cases.

The comparison of $\mathrm{ACO}_{\mathrm{KTS}}$ with best delivered results from macro cycle variant ( $\mathrm{ACO}_{\mathrm{MC}}$, Table 5) reveals $\mathrm{ACO}_{\text {KTS }}$ superior performance in each group (Table 14). The differences become larger with more resources available.

### 3.1.2 Results for the maximal path search

The graph, base parameters and reducing coefficient setting are the same as for the minimal path search case. Available resources, like number of ants and macro cycles, are in the Table 15. In each trial a different local optimum was found. Local optimum is given by the path $T_{\max }$ and it's length $L_{\max }$. Since each settings with 500 trials found different local optimum, results in Tables $16-26$ are extended by the length of the best solution $L_{\max }$ and arithmetic mean of all $L_{\max }$ values $\bar{L}_{\max }$.

Table 15: AVAILABLE RESOURCES PER GROUP

| Group | Ants | Macro cycles |
| :---: | :---: | :---: |
| 1 | 4 | 4 |
| 2 | 4 | 6 |
| 3 | 4 | 8 |

$\mathrm{ACO}_{\mathrm{VMC}}$ has a longer search process in each set, but the highest best value $\bar{L}_{\max }$ varies between $\mathrm{ACO}_{\mathrm{VMC}}$ and $\mathrm{ACO}_{\mathrm{Mc}}$. Constant values for the reducing coefficient cause decrease in performance. Better results were achieved with lower values of the reducing coefficient. It could even outperform variable settings with 0.05 for $\mathrm{ACO}_{\mathrm{VMC}}$ and with 0.02 for $\mathrm{ACO}_{\mathrm{MC}}$. Decreasing of the values of the reducing coefficient causes longer search process for $\mathrm{ACO}_{\mathrm{VMC}}$, but it did not have the same impact on $\mathrm{ACO}_{\mathrm{MC}}$.

The mean values for the termination cycle were taken form $\mathrm{ACO}_{\mathrm{VMC}}$ (Table 16) and were used for $\mathrm{ACO}_{\mathrm{KTS}}$ (Table 26). The results reveal $\mathrm{ACO}_{\mathrm{KTS}}$ outperforms $\mathrm{ACO}_{\mathrm{VMC}}$ in terms of $\bar{L}_{\text {max }}$ in each group. However, the difference is very small.

### 3.2 Test on the 62 node graph

The second graph is an asymmetric multi graph with 62 nodes and 114 arcs in which ants are allowed to take any arc in direction from the left to the right only. The start node is $n_{s}=62$ and the end node is $n_{e}=21$. Figure 4 shows the graph with the best path in red.

Figure 4: The 62 node graph with maximal path - red
The resources represented by number of ants and number of macro cycles are in Table 3. The reducing coefficient was set as variable. Notice that this graph was designed to lead the greedy algorithms out of the global optimum. Ant need to take arcs with low values and at the end it receives 300 on the last arc $a_{61,21}$.

All algorithms with all different parameter settings were able to find the longest paths \{62 42 $4344454647484950515253545556575859606121\}$ with value $L^{+}=300.2$. The only difference was in cardinality $n$ and arithmetic mean of the best value cycles $\bar{c}_{b e s t}$. As the test results show, there is a difference between $\mathrm{ACO}_{\mathrm{VMC}}$ and $\mathrm{ACO}_{\mathrm{MC}}$ (Table 27 and 29) performance. Thus test for $\mathrm{ACO}_{\text {KTS }}$ was running twice; once for termination cycles set according to $\mathrm{ACO}_{\mathrm{VMC}}$ (Table 28) and once according to $\mathrm{ACO}_{\mathrm{MC}}$ (Table 30). That allowed the performance cross comparison between both versions of ACO with macro cycles and $\mathrm{ACO}_{\mathrm{KTS}}$.

$\mathrm{ACO}_{\mathrm{MC}}$ leads to higher cardinality and longer search process only for limited resources, i.e. up to 6 ants and 4 macro cycles (Table 27, 29). Then $\mathrm{ACO}_{\mathrm{VMC}}$ higher cardinality and longer search process. The more resources are available the bigger the difference is.

The performance of $\mathrm{ACO}_{\mathrm{KTS}}$ is worse than any ACO variant with macro cycle, especially $\mathrm{ACO}_{\mathrm{VMC}}$ (Table 27, 28). The difference only increases with increasing number of resources.

## 4 Conclusion

In the 50 node graph path minimisation, $\mathrm{ACO}_{\text {KTS }}$ outperforms the $\mathrm{ACO}_{\mathrm{MC}}$. However, for maximal path search the difference between $\mathrm{ACO}_{\text {KTS }}$ and $\mathrm{ACO}_{\mathrm{VMC}}$ is very small. In the 62 node graph, where the success depends on finding a single well hidden global optimum, both variants ACO with macro cycles outperform $\mathrm{ACO}_{\text {Kts }}$.

In the 50 node graph, $\mathrm{ACO}_{\mathrm{MC}}$ outperforms $\mathrm{ACO}_{\mathrm{VMC}}$ for minimal path search. For maximal path search the best result varies between $\mathrm{ACO}_{\mathrm{MC}}$ and $\mathrm{ACO}_{\mathrm{VMC}}$. In the 62 node graph, $\mathrm{ACO}_{\mathrm{MC}}$ outperforms $\mathrm{ACO}_{\mathrm{VMC}}$ only with the use of limited resources. With more resources, $\mathrm{ACO}_{\mathrm{VMC}}$ outperforms $\mathrm{ACO}_{\mathrm{MC}}$ and the difference increases with increasing number of resources.

The influence of the reducing coefficient is significant. In general, constant values cause performance decrease. The lower the constant value is the better the performance is. However, only for maximal path search the low constant values are able to outperform results obtained with variable reducing coefficient.

In general, the here obtained results are promising. They show a performance potential compared to $\mathrm{ACO}_{\text {KTs }}$. Further improvement of ACO macro cycles variant will be achieved by longer search process. But the search process will have longer macro cycle instead of more macro cycles, which will allow better utilisation of already gathered knowledge. This will be obtained by reinitialisation shift to a later stage, i.e. between the saturation and stagnation phase. Further tests are
necessary to evaluate the impact of such modifications. However, the benefit of more intuitive input in number of macro cycles versus number of cycles can prevent from unnecessary long search process.
